

Migrating website to react.
Feature by feature.
Zero downtime.

Irmantas Zenkus | Frontend Team Lead | Kaunas

Evolution of our frontend app

Our first Frontend app

jQuery
jQuery-ui
twig

- All content is rendered server side
- Page is reloaded on each filter change
- Some small parts are fetched via ajax and html is replaced
- Classic approach to frontend

Why change that?

- Cannot update parts of page gradually without replacing large chunks
- One part of site cannot influence other part
- Hard to reuse some data from server side on different widgets
- Many unnecessary reloads

MVC architecture

jQuery
rivets
twig

- Separation of concerns
- Reusable M or V or C
- A lot of different ways for developer to write code
- We have less than 30 components

What did not work?

- A lot of different ways for developer to write code
- No control of how one component must call another
- Construction and destruction is difficult
- No lifecycle control of rivets.js view library
- Rivets.js library often forced us to choose less optimal solutions

Next architecture pilot project

- No matter how much you read and play around, you need to bring your code live at some point
- Small scale project with several difficult to do features
- Autocompleter
- Date picker
- Radio selector

Next architecture pilot project

webpack

TypeScript

Redux

React

Why redux?

- Popular yet do-one-thing-only library
- Easy to follow rules that have solid arguments
- Covers all cases we could think of
- Less different ways to write code

Why react?

- Does only one thing and does it really well
- Has an API that is not likely to change
- Is used live by large enterprises
- Is backed by large enterprise

Why typescript?

TypeScript

- No code comments are needed
- Can be maintained by a large group of developers
- Is backed by large enterprise

Road to React

- Start with modules that are self sufficient
- Pick the one that have the least dependencies
- If contract with rest of app is needed - use event manager
- Install performance and key business measurement code

Road to React

Islands of React

```
import { render } from 'react-dom';
import { Provider } from 'react-redux';
import store from './store';

render((
  <Provider store={store}>
    <Breadcrumb />
  </Provider>
), document.getElementById('breadcrumb'));

render((
  <Provider store={store}>
    <CurrencyChooser />
  </Provider>
), document.getElementById('currency-chooser'));

render((
  <Provider store={store}>
    <SearchSummary />
  </Provider>
), document.getElementById('search-summary'));
```

Road to React

Zero downtime

==

No decrease
of velocity

- Convert a module to redux only when changes for it are planned
- Make converted code as part of new feature being tested
- Run code to gather enough data
- Clean old code

Road to React

Minimal cost

- Islands of converted components formed
- Those are merged to form even bigger islands
- There is already a solid foundation of redux+react code
- Price for bussiness is minimal, since changes were planned anyway

Road to React

Islands
become
continents

```
import { render } from 'react-dom';
import { Provider } from 'react-redux';
import store from './store';

render((
  <Provider store={store} >
    <TopBar>
      <BreadCrumb />
      <CurrencyChooser />
      <SearchSummary />
    </TopBar>
  </Provide>
), document.getElementById('top-bar'));
```

Road to React

Challenges

- Gained trust and support from business developers
- “Install React” became business value
- Start working on Offers section and Map

Amenities **Wyndham Grand Clearwater Beach for Max.**

 Pool  Internet  Wheelchair access

 Spa

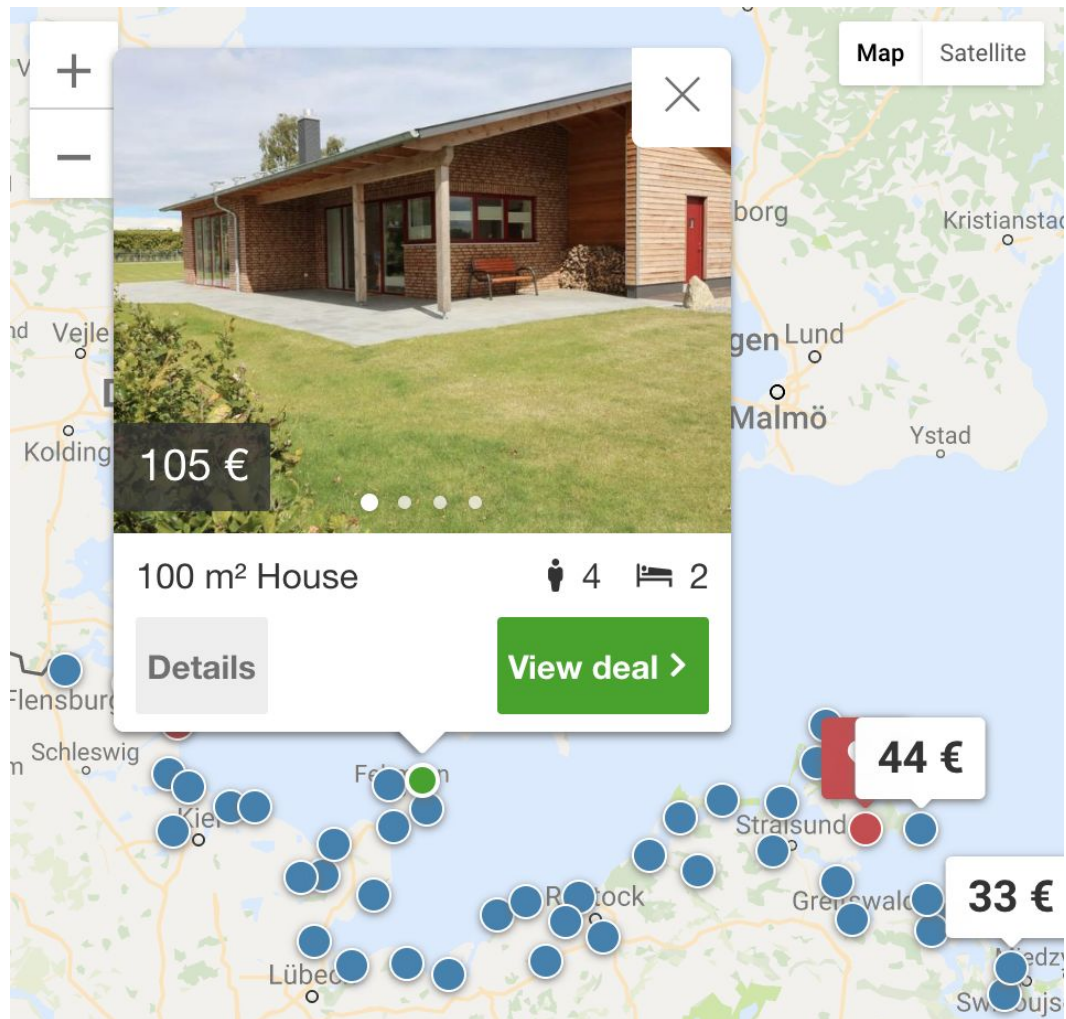

Description **Accommodation information**

Wyndham Grand Clearwater Beach, providing Distinctive & Tailored Experiences. Approachable by Design and the new signature centerpiece of Clearwater Beach. Visit Winter from "A Dolphin's Tale" at the nearby Clearwater Marine Aquarium or walk to the nightly Sunset Festival at Pier 60. The possibilities are as endless with 343 elegantly appointed guest rooms and suites, most with balconies and all overlooking the Gulf of Mexico or the Intracoastal Waterway. 22,000 sq. ft. of intimate meeting and function space, centered around the 10,632 sq. ft. Dunes Ballroom, the largest on the beach.

Road to React

Map

Road to React

Declarative
map

```
// google maps api
onMapReady(map) {
    map.addMarker(new MarkerOptions().position(new LatLng(10, 10));
}

// react-google-maps
<Map>
    <Marker key={1} />
    <Marker key={2} />
</Map>
```

Road to React

SPA must
have a router

- You want all dynamic content to be wrapped with a Router
- In our case we needed all page to be wrapped
- Search crawlers are not to trust to see your React rendered content

Road to React

Static content

```
class HtmlWrapper extends React.Component<Props, {}> {  
  render() {  
    const TagName = this.props.tagName;  
    return (  
      <TagName  
        id={this.props.id}  
        dangerouslySetInnerHTML={{ __html:  
this.props.staticHTML }}  
      />  
    );  
  }  
}
```

What is better?

- Whole application state is visible in one place
- At any given time there is just the minimal amount of DOM
- At any change of application state there is a minimal amount of computations and DOM updates
- Our RWD is mostly done with JS instead of CSS - more flexible
- Application has a solid structure and all developers know exactly where to find what

What could be better?

- Move as much computation as possible from reducer to thunks
- Have as little middlewares as you can
- Write tests for thunks only
- Separate components from containers
- Join several entry points into one app

Improve

Reducer with
logic

```
// reducer
handleActions({
  [RECEIVE_DATA]: (state, action) => {
    const items = action.payload.response.map((item) => {
      return {
        id: item.itemId,
        name: item.title
      };
    });

    return items;
  }
}, defaultState);
```

Improve

Logic within
thunk

```
//with thunk
const receiveData = (response) => (action, getState) => {
  const items = action.payload.response.map((item) => {
    return { id: item.itemId, name: item.title };
  });

  dispatch(setItems({ items }));
}

//reducer
handleActions({
  [SET_ITEMS]: (state, action) => {
    return action.payload.items;
  }
}, defaultState);
```

What could be better?

- Move as much computation as possible from reducer to thunks
- Have as little middlewares as you can
- Write tests for thunks only
- Separate components from containers
- Join several entry points into one app

Thanks
